

The most influential features affecting house price are **area**, followed by **number of bathrooms**, **air conditioning**, and **furnishing status**, indicating that both size and luxury amenities strongly drive pricing.

The Random Forest model performed better than Linear Regression, achieving higher accuracy (R^2 score) and lower prediction error, meaning it captures non-linear relationships more effectively.

Overall, the model provides reasonably accurate price predictions and is suitable for general estimation, though not perfect for exact valuation.

One interesting observation was that properties with similar area can still have significantly different prices due to amenities and location-related features.

From a business perspective, real estate companies should prioritize properties with larger area and premium facilities like AC and preferred locality, as these consistently command higher prices and better ROI.
